Project Parallax Whitepaper v2.0

25 Oct 2026 · @Reinis Pavlovs

About this version

Version 2.0 (25 October 2026) replaces version 1.0 of August 2026, which stated several hypotheses as established findings. Examples are that a model "proves" non-local consciousness and that perception during cardiac arrest is "verified". Those claims are withdrawn or reclassified here, and every figure below can be checked against its source.

The paper keeps the three layers the site uses for every topic: what has been measured or observed, how it has been interpreted, and what remains the author's hypothesis or an open question. The author's hypothesis is in Section 4 and feeds no score.

1. Purpose and scope

Project Parallax compares claims about consciousness, ancient engineering, cataclysms and cosmic structure with published evidence, and shows how much of each claim has been checked. It does not decide whether a claim is true.

Four topics are covered: near-death experiences and consciousness, structural similarity between neural and cosmic networks, acoustics of megalithic chambers, and cyclical catastrophism. The name comes from parallax: viewing one claim from two reference points, such as the supporter's reading and the skeptic's reading, gives a depth that one view cannot.

2. Method: three layers that are never merged

Checklist coverage. For each topic we list the questions a skeptical reader would ask, such as whether an independent replication exists or whether a measurement was made by someone with no stake in the result. Each item is scored satisfied (1), partial (0.5) or missing (0). An unresolved conflict between sources caps the total. The result is a coverage percentage with a class (A, B or C). **It is a measure of how much of the checklist has been worked through, not a probability that the claim is true.** A topic can score low because it has been little studied, or because the studies disagree; the class and the counts show which.

Literature corpus (near-death experiences only). Papers are collected from open indexes, passed through a relevance gate, and classified by what they report. In the current run 194 of 323 candidates were excluded as not relevant, and about 130 were analysed. The distribution is shown on the evidence page for the topic. The other three topics do not yet have a validated corpus pipeline; their pages say so rather than showing a number that would look more solid than it is.

Testimony corpus. 297 accounts from the Near Death Experience Research Foundation are kept as a separate layer. They are self-reports, and the project does not count them as evidence of the mechanism. We only ask how many contain a detail that could in principle be checked. Of 297 accounts, 95 (32.0%, 95% interval 26.9 to 37.5) have such a detail. Of those

95, none is confirmed, none is refuted, 77 are unverifiable from the available record and 18 have not yet been attempted.

Topic weights. A credibility-weighted Bayesian moving average over the individual claims (prior strength 20) produces a weight per topic, used only for ordering on the home page. It does not read the testimony layer.

Human review. Machine-drafted articles are published only after a named reviewer accepts them. Corrections are logged publicly and dated.

3. Current status by topic

Near-death experiences and consciousness: 58.3%, class B (3 items satisfied, 1 partial, 2 missing). Near-death experiences are common and well documented as reports. The AWARE I study (Parnia and colleagues, 2014) followed cardiac-arrest survivors across several hospitals; a small minority recalled awareness, and one case had an auditory report that could be checked against events. AWARE II (2023) found no correct identification of the hidden visual targets. The claim in version 1.0 that perception during a flat EEG is "verified" is withdrawn: no study has shown it, and a flat scalp EEG during arrest does not by itself establish what the brain is doing before and after the recording. Terminal lucidity is documented in case reports and reviews; its mechanism is unexplained, and the earlier wording that it "proves" an intact conscious core is withdrawn. Whether the experiences reflect brain activity or something beyond it remains open.

Megalithic acoustics: 33.3%, class B (0 satisfied, 4 partial, 2 missing). Resonance at roughly 110 Hz has been measured in several chambers, including the Hypogeum in Malta and Newgrange, by independent teams. What has not been shown is that the resonance was intended, that it produces measurable effects on people beyond ordinary acoustic experience, or that stone converts sound into electromagnetic signals in a way that carries information. The claim of a global piezoelectric waveguide is withdrawn as unsupported.

Neural and cosmic networks: 33.3%, class B (1 satisfied, 2 partial, 3 missing). Vazza and Feletti (2020) compared the cerebellum with the cosmic web and found similarities in some statistical measures over limited ranges of scale. The authors attribute this to the general behaviour of self-organising systems, not to a shared mechanism or deeper identity. Version 1.0 called the match "mathematically indistinguishable" and said it "validates" a philosophical claim; both are withdrawn.

Cyclical catastrophism: 25.0%, class C, capped by a conflict (0 satisfied, 3 partial, 2 missing, 1 conflict). The Younger Dryas impact hypothesis remains contested; its evidence layers have been disputed and defended in the literature. Mainstream archaeology does not support a vanished advanced civilisation. The statements in version 1.0 about a fully formed Egyptian mathematics, a pole shift of more than 50 km per year and a closing precession cycle are withdrawn or moved to Section 4 as hypothesis.

4. The author's hypothesis, kept separate

The project began from a personal view: that consciousness may not be produced by the brain alone, and that ancient builders may have understood something about resonance and cycles

that we have lost. This is a hypothesis. It is not a finding of this project, it feeds no score on the site, and readers who disagree with it can use every other section unchanged.

Ideas from version 1.0 that now sit here and nowhere else include the brain as a filter of a non-local field, access to a shared morphogenetic field in resonant chambers, travelling master builders after the Younger Dryas, and a convergence around 2026. None has direct empirical support in the sources reviewed.

What would change our minds. Each direction has a test.

- A hidden-target result in a controlled cardiac-arrest study, correctly reported above chance in a pre-registered design, would raise the consciousness topic substantially.
- A pre-registered study showing that resting EEG and later recall fully account for reported experiences would lower it.
- Evidence that chamber resonances were tuned, for example repeated frequencies across independent sites that are unlikely by chance, would raise the megalith topic. Resonances explained by cavity size alone would lower it.
- Independent replication of the Younger Dryas boundary markers by laboratories with no stake in the result would raise the cyclical topic; failure to replicate would lower it.

If a test is met in either direction, the coverage figure and this paper will be updated and the change logged.

5. Open data, contributions, limits and citation

Data formats. The project accepts research data in open formats: 24-bit/96 kHz WAV for chamber recordings, EDF or EDF+ for EEG, and CSV for coordinates, azimuths and stellar alignments. Contributions are reviewed with the same checklist as any other source, and the provenance of each file is recorded.

Limits.

- The coverage percentage depends on a checklist written by one person. The checklists are published so others can dispute them.
- Only one topic has a literature corpus, and its relevance gate and classifier were tuned on that topic.
- The testimony layer is drawn from one site, with permission requested and not yet confirmed in writing for all uses.
- Machine classification can be wrong. A named human reviews each published article, and corrections are logged.
- Nothing here is medical, legal or financial advice.

Contact and updates. Corrections, data and criticism are welcome through the site at www.myparallax.org. Each change to this paper will be listed in the public correction log.
